ABSTRACT

Pure Wogonin (5,7-dihydroxy-8-methoxyflavone) as well as part of different extracts from *Scutellaria* (Lamiaceae) genus plants, has demonstrated to possess anti-inflammatory, anti-cancer, antiulcer, neuroprotective, anti-atherosclerotic, anti-arthritic, anti-tumor, anti-allergic, anticoagulant, antioxidant and antiviral properties. Because of the growing interest in this substance, many methods for its isolation and high purity have been developed and reported in the literature. However, such methods are laborious, inefficient and expensive. In the present investigation, two new fast, selective and ship methods for isolating pure wogonin with high yields from *Scutellaria havanensis* were developed. The methods involve fresh aerial parts extraction with ethyl ether by sonication (5 min) and electrical shaker (2h), filtration and solvent evaporation without using any chromatographic techniques. Quantities of ca 0.8 to 1.2 g of wogonin (>95 % purity) were obtained from 50 g of plant material, yielding 8 to 12 % of recoveries (dry weight). The structure of wogonin was confirmed by PMR and 13C-NMR, UV, FT-IR and GC-MS. This is the first report on the wogonin isolation and characterization from this endemic Cuban plant by simple extraction and direct crystallization from the extract.

Keywords: *Scutellaria havanensis*, wogonin, Lamiaceae, NMR, GC-MS, ultrasound.

INTRODUCTION

*Scutellaria* (Lamiaceae) genus is widely distributed throughout the world and it is represented by about 300 species. 1-5 Several pharmacologic researches have confirmed that total extracts or flavones of this genus, such as wogonin (5,7-dihydroxy-8-methoxy flavone) and baicalen (5,6,7-trihydroxyflavone) possess anti-inflammatory,6-10 antiulcer,11-14 neuroprotective,15-19 anticonvulsant,18-19 antithrombotic,20,21 antioxidant,22,23 anticancer,24 antitumor,25 anti-arthritic,26 antiviral, anti-allergic, antispasmodic and antimicrobial properties.27,28,29

Considering wogonin’s pharmacological relevance and the fact that it occurs together with other flavonoids in the different parts of *Scutellaria* species,29-33 several trials have been carried out for its isolation and production, even at large scale. Among them, increasing the growth rate and flavonoid content of *Scutellaria* species with CO2 enrichment in a controlled environment,34 cultivation of *Scutellaria* cells,35-37 synthesis methods,38 biotechnology production,39,40 classical column chromatography methods, analytical assay,31,32,41 and preparative high-performance liquid chromatography,22 high-speed countercurrent chromatography42 and a low-pressure preparative chromatography (LPPC) after endogenous baicalinase catalyzed hydrolysis.43 However, these methods have disadvantages of a long extraction time, low yield of wogonin, high solvent consumption, multiple steps for the isolation, high cost of the procedures and very laborious ones.

*Scutellaria havanensis* Jacq. (Havana skullcaps) is an endemic plant native in Havana, Cuba.44 Until present days, a qualitative phytochemical screening of the ethereal, methanol and aqueous extracts45 as well as the study of the volatile constituents46 from aerial parts of this plant have been performed. In this work, flavonoids, alkaloids, coumarins, triterpenoids and steroids, alkaloids, free amine groups, sugars, quinones, resins, saponins and bitter principles were detected, besides 8-caryophyllene (75.6%), α-humulene (11.6%), caryophyllene oxide (2.6%) among other volatile compounds in minor proportions were identified. A total absence of anthracenic and cianogenetic glycosides was also demonstrated. Continuing the investigation of Cuban Lamiaceae, in the present paper we report two new specific and single methods for obtaining pure wogonin with high yield from aerial fresh parts of *S. havanensis*.

MATERIALS AND METHODS

Plant material

Aerial parts (leaves and stems) of *S. havanensis* were collected in October 2011 in the National Botanic Garden, Havana, Cuba. Identification of the plant material was carried out by PhD. Angela Leyva (voucher 087485-HAJB).

Wogonin extraction and analysis

Fresh aerial parts (leaves and stems) of *S. havanensis* (50 g) were extracted with diethyl ether (100 mL) for 2 h in an electrical shaker (ZRM, CNIC, Cuba) at room temperature and for 15 min in an ultrasonic bath (35 KHz, Bioblock Scientific, Germany). After filtering the extracts, the solvents were evaporated at room temperature to yield...
only yellow needles in high percent. Methods were applied three times. The purity of the yellow needles was evaluated by GC-MS and chemical structure elucidate with all spectroscopic techniques available.

Equipment

Melting point (m.p.) was determined on a Reichert-Thermovar apparatus (Germany). UV-spectrum was recorded on a Spectron 8000 (Thermo Electron, USA). IR spectrum was recorded on a Biorad FTS-60A spectrophotometer (USA). Mass spectrum was recorded on a Hitachi QP 2010 plus spectrometer (Japan). NMR spectrum was recorded on a Bruker DPX-300 spectrometer (USA). Other spectroscopic data and chemical shifts were obtained using a Bruker AVANCE III 500 spectrometer (Germany) and thermometer was kept at 60 °C for 5 min. The injection and source temperature were 320 °C and 250 °C, respectively. MS interface temperature was 250°C. EI/MS spectrum was taken at 70 eV. Mass range was from m/z 35 to 800. Peak identification was achieved by computer matching mass spectra against commercial libraries (NIST 2011 GC/MS), as well as MS literature data. 

RESULTS AND DISCUSSION

Because of the current interest in Wogonin (Fig 1) as well as the low proportions at which this flavone has been detected and isolated so far, (0.01 - 0.12 %) either in the different parts of the Scutellaria plants (S. baicalensis, S. laterifolia, S. barbata) among others, or in their commercial products, in the present investigation were developed two new, simple and rapid procedures for selective isolation of pure wogonin from the fresh aerial parts of Scutellaria havanensis without using any chromatographic or other isolation techniques.

As it was previously described, after a single extraction, using fresh plait material, with diethyl ether, filtration and solvent elimination, yellow needles were obtained, with high percent recovery of the flavonoid based on dry plant material (Table 1). Higher recoveries were reached too, when ultrasonic bath was employed for extraction, using fresh plant material, while reducing significantly the extraction time. It was also noted that both methods were reproducible, batch to batch, and high yield of wogonin were obtained in comparison to other reported methods developed for the same purpose. By the contrary, those methods previously mentioned, are time-consuming and expensive, whereas in case of 8-methoxy derivatives [M + CH3]+ ions have higher intensities (90-100%) than [M]+ while [M-H2O]+ fragments show only very small intensities or are not present at all.

Other spectroscopic data and physical constants which confirm that the isolated compound was 5,7-dihydroxy-8-methoxyflavone or wogonin (Fig.1) are: Yellow needles: mp 203–204°C. UV spectrum (MeOH, λ max, nm): 245, 276, 316. IR spectrum (v, cm–1): 3460–3230 (OH), 2925 (OCH3), 1661 (C=O), 1615 and 1580 (C=C). PMR spectrum (250 MHz, DMSO-d6, δ, ppm, J/Hz, 0 = HMDS): 3.88 (3H, s, OCH3), 6.32 (1H, s, H-3), 6.86 (1H, s,H-6), 7.60 (3H, m, H-2’,4’,6’), 8.01 (2H, d, H-3’,5’), 12.39 (1H, s, 5-OH).

Harbone, reported that this type of flavonoid occurs in the outside of the leaves of the plant so when previous methylation is used, it is possible the isolation using solvents of middle polarity. According to this, wogonin has been detected in ethyl acetate in S. schachristanica and dichloromethane in S. baicalensis. In addition, empirical evidence and practical work, have both indicated that fresh herb extraction is likely to be more efficacious than the dried herb, because the instability of the latter and the presence of fewer flavonoids content. This report supports the results of the extraction methods used in the present investigation.

The obtained yellow needles were characterized by the spectral data (GC-MS, UV; IR, PMR and 13C NMR) as well as a comparison with the literature reports, allowing to identify the product as 5,7-dihydroxy-8-methoxyflavone or wogonin with over 95% of purity directly from the extracts (Fig 1). Thus, the GC-MS analysis indicated the presence of a single major component; its retention time was 20.98 min (Fig. 2a).

The molecular formula was established as C21H22O8 based on EI/MS (Fig. 2b) that showed the presence of molecular ion (M+) in m/z 284 Dalton (54.2 %), other important ions were detected at m/z 269 [M-Me] (base peak, 100%), 283 [M+1] (10%), 139 [A1-Me-CO] (38.7%), 241 [M-43-Me-CO] (26.7%), 69 (12.3), 103 (7), 254 [M-OCH2] (8%), 209 [2-M-PH] (6.4%), and 167 [A1-Me] (6.9%). Fragmentation pattern was carried out according to Mabry and Markham. The 8-methoxy position was also established because of the fact that 6-methoxylated aglycones (flavones) still exhibit intensive fragments at both [M-CH3] (32-56%) and [M-H2O] (42-29.5%), whereas in case of 8-methoxy derivatives [M-CH3] ions have higher intensities (90-100%) than [M]+ while [M-H2O] fragments show only very small intensities or are not present at all.

**CONCLUSION**

Two fast, selective and ship methods for the isolation of pure wogonin with high yields, directly from the extracts of fresh plant material of \( S. \) havanensis were developed. The results of the present investigation indicated that the developed procedures are efficient methods for obtaining pure wogonin without using any chromatographic techniques directly from extracts. This compound is reported for the first time from the aerial parts of this specie that grow in Cuba. These results are a contribution to the chemical composition of this endemic Cuban plant and could support future research on its possible pharmacological effects.
