ABSTRACT

Scheleichera oleosa is (Lour.) Oken belonging to the family Sapindaceae. The anti-inflammatory and anti-arthritic effect of ethanolic extract of bark of Scheleichera oleosa was evaluated in various experimental models in rats and mice. Anti-inflammatory activity was studied by Acetic acid induced writhings, Cotton pellet granuloma and Antiarthritic activity was accessed in Freund’s adjuvant induced paw oedema in rats (n=6) by SOEE (in doses of 200 mg/kg, 400mg/kg and 600 mg/kg of body wt.). Indomethacin was used as standard drug for both the activities. SOEE of doses proved significant (P < 0.05, P<0.01, P<0.001) decreases in writhings in mice and also decreases in dry weight of cotton in anti-inflammatory activity models. The extract doses showed significant (P<0.001, p<0.01) reduced paw oedema in dose dependent manner in carrageenan induced rats. The results obtained from the present study showed that the ethanolic extract of S.oleosa has anti-inflammatory and anti arthritic activity.

Keywords: Anti inflammatory, Antiarthritic, Scheicherooleosa, Complete Freund’s adjuvant emulsion (CFA).

INTRODUCTION

Inflammation is a physiological process in response to tissue damage resulting from microbial pathogen infection, chemical irritation & wounding. Inflammation is a normal response to any noxious stimulus that threatens the host and may vary from localized response to a generalized one. The inflammatory process protects our body from diseases by releasing cells and mediators that combat foreign substances and prevent infection. Inflammatory response is a complex process mediated by variety of signalling molecules released by nerve endings, mast cells, platelets and leukocytes. Basically arthritis involves the breakdown of cartilage (normally protects a joint, allowing it to move smoothly), that also absorbs shock when pressure is placed on the joint, as during walking. Without the normal amount of cartilage, the bones rub together, causing pain, swelling (inflammation), and stiffness and limited movement. The need of treatment is to reduce pain, improve function, and prevent further joint damage.

Rheumatoid arthritis (RA) is considered the most common chronic inflammatory autoimmune disease. Rheumatoid arthritis consists of synovial joint inflammation, leading to bone and cartilage destruction. Early aggressive treatment to manage symptoms and slow disease progression include disease-modifying antirheumatic drugs (DMARDs), adjunctive non-steroidal anti-inflammatory agents and corticosteroids, physical therapy, exercise and rest.

Scheleichera is a monotypic genus of plants in the family, Sapindaceae. S. oleosa is a tree and commonly known as Kusum that occurs in the Indian subcontinent and Southeast Asia. The oil extracted from the seed, called ‘kusum oil’ is used for cooking and lighting purpose, cure of itching, acne, burns, other skin troubles, rheumatism (external massage), hair dressing and promoting hair growth. The bark is used as an astringent and against skin inflammations, ulcers, itching, acne and other skin infections. It is generally used as an analgesic, antibiotic and against dysentery. Various studies were also done to find out the various constituents of S.oleosa phytochemical studies have shown that its bark contains lupeol, lupeol acetate, betulin, betulinic acid, beta-sitosterol, and scopoletin. From derivatives of lupane series, betulin and betulnic acid are the most effective compounds in skin inflammation. Betulnic acid shows significant anti-inflammatory activity against rat paw oedema induced by carrageenan and serotonin, which is comparable to the standard anti-inflammatory agents. Betulin and betulnic acid inhibited phospholipase A2 and showed the anti-inflammatory activity.

MATERIALS AND METHOD

Collection of Plant material

The stem bark powder of the plant was procured by K. Madhava Chetty, Assistant Professor, Dept. of botany, Sri Venkateswara University, Tirupati and authenticated by Prof. Dr.Vatsavaya S. Raju, M.Sc., Ph.D., D.A.S., FBS., FIAT from the Dept. Of Botany, Kakatiya University, Warangal, AP. A voucher specimen (Voucher No. 1900) has been
Preparation of Bark Extract

The coarse powder was extracted with ethanol using cold percolation method.

Cold percolation method

A known amount of the dried material (5gm/50mL) was soaked in ethanol and kept for occasional shaking nearly 48hrs using percolator. This was followed by filtration by using filtration and evaporation of excess solvent without applying heat. The obtained dried extract was stored at 4°C and obtained extract yield after dried was approximately 2.5gms for 25 Gms of bark powder.

Preliminary Phytochemical Screening

The ethanolic extract was screened for the presence of various phytochemical constituents like Flavonoids, terpenoids, steroids, tannins and phenolic compounds by using standard phytochemical tests.

Animals

Sparagedawely rats (weighing 150-250gms & age 2-3 months) and Swiss albino mice (weighing 20-25gms & age 7-9 weeks) of either sex were used in this study. They were procured from Mahaveer Enterprises, Hyderabad. The animals were acclimatized for one week under laboratory conditions. They were housed in polypropylene cages and maintained at 22-27± 2°C under 12hrs dark/light cycle. They were fed with standard rat pellet feed and hygiene maximum comfort for animals. Animals Ethics Committee (Reg.1629/PO/a/12/CPCEA) and approval No 002/IAEC/NCPA/M.Pharm/2013-14) for the care and use of animals and were strictly followed throughout the study.

Acute Toxicity studies

Acute oral toxicity was performed as per OECD-423 guidelines. The purpose of these studies is to know the safety & toxicity of the extract doses. For this study, Swiss albino mice of weights 20-25g were selected & divided into 6 groups, each group consisting 6 animals. The animals were fasted overnight with free access of water ad libitum. The Schleichera oleana (Lour.) Oken extract was suspended in CMC and administered to all the 6 groups at doses 100, 300, 500, 1000, 1500 and 2000 mg/kg doses orally. The animals were closely observed for 24hr for any behavioural, physical changes and mortality. Doses were fixed based on acute toxicity studies.

Anti-inflammatory activity

Acetic acid induced Wriths method

The Swiss albino mice (20-25gms body weight and 7-9 weeks age) were divided into 5 groups. SOEE (200m/kg, 400mg/kg, 600mg/kg body wt., p.o each) and Indomethacin (5mg/kg body wt., p.o) was administered one hour prior to i.p. injection of 0.1mL of 1% acetic acid. Five minutes after the intra-peritoneal injection, the number of writhings during the following 10 min was counted. Finally the percent analgesic effect was determined. The number of writhings and stretching’s was recorded and the percentage was calculated.

The percent inhibition (% anti-inflammatory activity) was calculated by

\[
\% \text{ inhibition} = \frac{N-N_t}{N} \times 100
\]

Where, \( N \) = Average number of stretching of control per group.

\( N^t \) = Average number of stretching of test per group.

Cotton Pellet Granuloma method

Procedure:

Male Sprague Dawely rats with an average weight of 180-200 g and age 2-3 months were anaesthetized with ether. The back skin was shaved and disinfected with 70% ethanol. An incision is made in the lumbar region. By a blunted forceps subcutaneous tunnels were formed and a sterilized cotton pellet weighing 15mg was placed on both sides in the scapular region. The pellets are either standardized for use in dentistry formed from raw cotton which produces a more pronounced inflammation than bleached cotton. The animals are treated for 7 days orally. Then, the animals are sacrificed, the pellets prepared and dried until the weight remains constant. The net dry weight, i.e. after subtracting the weight of the cotton pellet is determined. The average weight of the pellets of the control group as well as of the test group was calculated. The percent change of granuloma weight relative to control group was determined.

The percent inhibition (% anti-inflammatory activity) was calculated by

\[
\% \text{ inhibition} = \frac{N-N_t}{N} \times 100
\]

Where, \( N \) = Average number of stretching of control per group.

\( N^t \) = Average number of stretching of test per group.

Anti-arthritic activity

A. Complete Freund’s adjuvant induced oedema

Sprague dawely rats of either sex of age 2-3 months, weighing 180-200 g and were divided into 6 groups. The 1st group as control group and 2nd one as positive control group. The 3rd group received standard drug Indomethacin at a dose of 10mg/kg per oral. The 4th, 5th and 6th groups received SOEE 200mg/Kg, 400mg/Kg and 600mg/Kg each respectively by oral route. After 30 min of 0.1mL CFA injection into the sub plantar region of left hind paw on ’0’ day, Standard Indomethine (10mg/kg p.o.) and extracts were administered orally once daily till 21st day.
The anti-arthritic effect of the extracts as well as standard evaluate by measuring paw volume of inject paw on 4th, 8th, 14th, and 21st day of study by using plethysmometer. The mean changes in injected paw volume with respect to initial paw volume were calculated on respective days and % inhibition of paw volume with respect control group was calculated. The changes in body weight record daily. On the day 22nd blood was withdrawn from the each the animal through retro-orbital vein puncture by anaesthetizing the animal with ether. The blood was collected into vials containing EDTA and the biochemical parameters like haemoglobin content, WBC count, and RBC analysed.

RESULTS AND DISCUSSION

Acetic acid induced Wriths method

Table: 1: Effect of S.oleosa (200, 400 and 600 mg/kg) on Acetic acid induced Wriths method in mice:

<table>
<thead>
<tr>
<th>Groups</th>
<th>Treatment</th>
<th>No. of Wriths</th>
<th>% inhibition</th>
</tr>
</thead>
<tbody>

<tr>
<td>V</td>
<td>1% A.a+ SOEE-600mg/Kg (p.o)</td>
<td>10.8±0.600***</td>
<td>73.1</td>
</tr>
</tbody>
</table>

Pretreatment of mice with standard Indomethacin (5mg/Kg) and doses of SOEE (200, 400, and 600mg/Kg p.o) significantly (**P<0.001) reduced in acetic acid induced writhing in a dose dependent manner which are 24.6%, 63.4% and 73.1% in that doses sequence, although the standard dose was 53.5%. The number of writhing and stretching’s of extract and standard doses were compared to acetic acid infused control. Acetic acid induced writhing elucidated as peripheral analgesic activity. Acetic acid causes analgesia by liberating endogenous substances and many others that excite pain at nerve endings. There writhing are related to increase in the peritoneal level of prostaglandins and leukotrienes. The results suggest that mechanism of action of extract may be linked to lipooxygenase and/or cyclooxygenase.

Cotton Pellet granuloma method

The Cotton Pellet Granuloma model elicited to assess the ability of inflammatory effects of the Proliferative components of chronic inflammation. Treatment $S.oleosa$ (200, 400, and 600mg/Kg p.o) to rats revealed a significant (**P<0.001) inhibition in the dry weight of cotton pellet against to cotton implantation control group.
and % inhibition was found to be 35.46 %, 60.85% and 66.6% correspondingly.

The observations are mean ± S.E.M. ***P<0.001 as compared to control. 

(Two way ANOVA followed by Bonferroni post tests).

The reference standard (Indomethacin 10mg/Kg) inhibition was 46.75%. The S.oleosa decrease in the size of the granuloma may be because of the way of inhibitory action of granulocyte infiltration, preventing generation of collagen fibres and by suppression of mucopolysaccharide.

**Anti-arthritic Activity**

In CFA model the observations such as paw volumes and body weights recorded on 1\textsuperscript{st}, 4\textsuperscript{th}, 8\textsuperscript{th}, 14\textsuperscript{th}, and 21\textsuperscript{st} days after adjuvant injection. The increase in the paw volume (arthritus one of the signs enhanced) observed in CFA induced Arthritis control group which indicates primary and secondary arthritic lesion. Another observation decreased body weight also indicates the induction of arthritis in CFA control group of rats. The evaluation finished on the 21\textsuperscript{st} day showed that the standard and S.oleosa treatment had significantly (***P<0.001, **P<0.01) reduced the paw volumes and increase in body weights in the respective treatment groups as compared with the CFA control group. The percentage inhibition of paw volumes on 21\textsuperscript{st} day, standard Indomethacine (10mg/Kg, p.o.) was 40%, 200mg/kg, 400mg/Kg and 600mg/Kg doses of SOEE were 34%, 36% and 40% respectively compared against positive control.

The haematological parameters such as an increase in the WBC count, decrease in RBC count and increased Hb % were in CFA induced group also analysed in S.oleosa and standard treated group. Recent studies have revealed the key roles of pro-inflammatory cytokines, such as tumor necrosis factor-a (TNF-a), interlukin-1b (IL-1b), IL-6 and IL-8 in the pathogenesis of RA. In the present study, we showed that ethonolic extract at a dose of 200, 400 and 600mg/Kg body weight significantly inhibit the progression of the rheumatoid arthritis in treated animals. The effect of the extract was dose dependent.

CONCLUSION

Based on the present study, it can be concluded that SOEE has potential anti-inflammatory effects and anti-arthritic activity comparable to those observed with standard drugs. The mechanism of action might be associated with the inhibition of prostaglandins synthesis as observed for most NSAIDs. Further isolation of active constituents and investigation of SOEE is required to study the detailed mechanism of action with different pain and inflammation models in relation to prostaglandin synthesis. My study shows that SOEE has potential to be developed as a new product for pain & inflammation management.
