ABSTRACT

Twelve male Wistar rats (120 - 140 g) were divided into control (distilled water) and losartan-treated (0.71 mg/kg) groups (6 per group) for hormonal assay, andrological and histopathological studies. The animals were orally treated on daily basis for 50 days. Plasma testosterone level was assayed using Enzyme-linked Immuno-sorbent Assay (ELISA) and semen analysis was done microscopically. Histology of testes was also done. Data were analysed using descriptive statistics and ANOVA at p=0.05. Treatment of rats with losartan (0.71 mg/kg) produced no significant (p>0.05) change in testosterone level relative to control. Treatment of rats with losartan (0.71 mg/kg) caused significant (p<0.05) reductions in progressive sperm motility and sperm count relative to their respective controls. It can therefore be concluded that losartan probably have deleterious effect on the reproductive functions in male rats.

Keywords: Losartan, Testosterone, Sperm motility, Sperm counts, Rats.

INTRODUCTION

Losartan is an angiotensin II receptor antagonist drug used mainly to treat high blood pressure (hypertension). Losartan may also delay progression of diabetic nephropathy and is associated with a positive clinical outcome in that regard. It is a suitable pharmacological agent for the reduction of renal disease progression in patients with type 2 diabetes, hypertension, and microalbuminuria or proteinuria. Losartan has been reported to have a protective effect in mice with chronic viral myocarditis induced by coxsackievirus B3. Its additive effect of in (mREN-2)27 transgenic rats has been reported. Acute peripheral administration of losartan has been reported to decrease striatal dopamine levels in rats. It has been reported that losartan reduced ensuing chronic kidney disease and mortality after acute kidney injury in mice. The inhibitory effect of losartan on increased leucocyte entrapment in retinal microcirculation of diabetic rats has also been reported. Losartan attenuates renal interstitial fibrosis and tubular cell apoptosis in a rat model of obstructive nephropathy as well as inhibits collagen I synthesis and improves the distribution and efficacy of nanotherapeutics in tumors.

However, due to paucity of information from literature on the effect of losartan on reproductive parameters in male rats, this study therefore aims at investigating the effect of this antihypertensive agent on these aforementioned parameters in male rats.

MATERIALS AND METHODS

Experimental Animals

Adult male rats weighing between 120 – 140 g bred in the Pre-Clinical Animal House of the College of Medicine and Health Sciences, Afe Babalola University were used. They were housed under standard laboratory conditions and had free access to feed and water; they were acclimatized for two weeks to laboratory conditions before the commencement of the experiments. All experiments were carried out in compliance with the recommendations of Afe Babalola University Ethics Committee on guiding principles on care and use of animals.

Drug

Angiotensin II receptor antagonist (losartan) tablets (TEVA UK, Ltd.) were bought from Danax Pharmacy, Ibadan, Nigeria.

Losartan (50 mg) was dissolved in 10 ml of distilled water to give a concentration of 5.0 mg/ml.

The dosage of losartan used in this study was in accordance with that recommended by the manufacturer.

Body Weight

Body weight was monitored on weekly basis throughout the duration of the experiment for each rat.

Experimental Design

Twelve male rats (120 – 140 g) were randomly divided into two groups, with each consisting of six animals. The two groups were subjected to the following oral treatments once a day for fifty (50) days:

1 Losartan (50 mg) was dissolved in 10 ml of distilled water and was given at a concentration of 5.0 mg/ml.

2 Distilled water was given at a concentration of 5.0 mg/ml.

3 Losartan was administered via oral gavage once a day for fifty (50) days.

4 Distilled water was administered via oral gavage once a day for fifty (50) days.
Group I: received 0.5 mL/100 g of distilled water as control group.

Group II: received 0.71 mg/kg of losartan.

**Collection of Blood Samples**

Twenty four hours (day 51) after the last dosing of the groups, blood samples were collected from all the animals through the medial canthus for the determination of plasma testosterone levels. All the animals were later sacrificed by an overdose of diethyl ether and the testes were removed along with the epididymis for semen analysis.

**Hormonal Assay**

Plasma samples were assayed for testosterone using the enzyme-linked immunosorbent assay (ELISA) technique using the Fortress kit.

**Semen Collection**

The testes were removed along with the epididymides. The caudal epididymides were separated from the testes, blotted with filter papers and lacerated to collect the semen.

**Semen Analysis**

**Progressive sperm motility:** This was done immediately after the semen collection. Semen was squeezed from the caudal epididymis onto a pre-warmed microscope slide (27°C) and two drops of warm 2.9% sodium citrate was added, the slide was then covered with a warm cover slip and examined under the microscope using x400 magnification. Ten fields of the microscope were randomly selected and the sperm motility of 10 sperms was assessed on each field. Therefore, the motility of 100 sperms was assessed randomly. Sperms were labelled as motile, sluggish, or immotile. The percentage of motile sperms was defined as the number of motile sperms divided by the total number of counted sperms (i.e. 100)°.

**Sperm viability (Life/dead ratio):** This was done by adding two drops of warm Eosin/Nigrosin stain to the semen on a pre-warmed slide, a uniform smear was then made and dried with air; the stained slide was immediately examined under the microscope using x400 magnification. The live sperm cells were unstained while the dead sperm cells absorbed the stain. The stained and unstained sperm were counted and the percentage was calculated 10°.

**Sperm morphology:** This was done by adding two drops of warm Walls and Ewas stain (Eosin/Nigrosin stain can also be used) to the semen on a prewarmed slide, a uniform smear was then made and air-dried; the stained slide was immediately examined under the microscope using x400 magnification 10°. Five fields of the microscope were randomly selected and the types and number of abnormal spermatozoa were evaluated from the total number of spermatozoa in the five fields; the number of abnormal spermatozoa was expressed as a percentage of the total number of spermatozoa.

**Sperm count:** This was done by removing the caudal epididymis from the right testes and blotted with filter paper. The caudal epididymis was immersed in 5mL formol-saline in a graduated test-tube and the volume of fluid displaced was taken as the volume of the epididymis. The caudal epididymis and the 5mL formol-saline were then poured into a mortar and homogenized into a suspension from which the sperm count was carried out using the Improved Neubauer haemocytometer under the microscope.

**Testicular Histology**

After removing the testes, they were immediately fixed in Bouin’s fluid for 12 hours and the Bouin’s fixative was washed from the samples with 70 % alcohol. The tissues were then cut in slabs of about 0.5cm transversely and were dehydrated by passing through different grades of alcohol: 70 % alcohol for 2 hours, 95 % alcohol for 2 hours, 100 % alcohol for 2 hours, 100 % alcohol for 2 hours and finally 100 % alcohol for 2 hours. The tissues were then cleared to remove the alcohol, the clearing was done for 6 hours using xylene. The tissues were then infiltrated in molten Paraffin wax for 2 hours in an oven at 57°C, thereafter the tissues were embedded. Serial sections were cut using rotary microtome at 5 microns (5 μm). The satisfactory ribbons were picked up from a water bath (50°C-55°C) with microscope slides that had been coated on one side with egg albumin as an adhesive and the slides were dried in an oven. Each section was deparaffinized in xylene for 1 minute before immersed in absolute alcohol for 1 minute and later in descending grades of alcohol for about 30 seconds each to hydrate it. The slides were then rinsed in water and immersed in alcoholic solution of hematoxylin for about 18 minutes. The slides were rinsed in water, then differentiated in 1% acetic acid and then put inside a running tap water to blue and then counterstained in alcoholic eosin for 30 seconds and rinsed in water for a few seconds, before being immersed in 70 %, 90 % and twice in absolute alcohol for 30 seconds each to dehydrate the preparations. The preparations were cleared of alcohol by dipping them in xylene for 1 minute. Each slide was then cleaned, blotted and mounted with DPX and cover slip, and examined under the microscope. Photomicrographs were taken at x40, x100 and x400 magnifications

**Statistical Analysis**

The mean and standard error of mean (S.E.M.) were calculated for all values. Comparisons between the control and the treated groups were done using one-way analysis of variance (ANOVA) with Duncan’s Multiple Range Test. Differences were considered statistically significant at p<0.05.
RESULTS

Effect on Body weight

Treatment of rats for fifty days with losartan (0.71 mg/kg) produced no significant (p>0.05) changes in body weight throughout the duration of treatment (Figure 1).

![Figure 1: Body weight changes in control rats and rats treated with losartan for 50 days (n=6, p<0.5)](image1)

Effect on Plasma Testosterone Level

Treatment of rats for fifty with losartan (0.71 mg/kg) produced no significant (p<0.05) change in testosterone level relative to control (Figure 2).

![Figure 2: Effect of treatment of rats for 50 days with losartan on plasma testosterone level (n=6, p<0.5)](image2)

Effect on Sperm Characteristics

The effect of 50 days treatment of rats with losartan (0.71 mg/kg) on sperm characteristics are shown in Figures 3 and 4.

Treatment of rats with losartan (0.71 mg/kg) caused significant (p<0.05) reductions in progressive sperm motility, but produced no significant changes (p>0.05) in the percentage of viable sperms relative to their respective controls. Treatment of rats with losartan (0.71 mg/kg) caused significant (p<0.05) increase in the percentage of abnormal sperms, as well as induced significant (p<0.05) reductions in sperm count relative to their respective controls.

![Figure 4: Spermogram showing the effect of 50 days treatment of rats with losartan on sperm counts (n=6, p<0.05)](image4)

Histopathological Effect

Plates 1 and 2 respectively show the transverse sections through the testes of control rat and rat treated with losartan (0.71 mg/kg) for fifty days.

![Plate 1](image1)

![Plate 2](image2)
Treatment of rats with losartan caused no visible lesion in the testes of rats, which is similar to what was observed in the control rats.

Photomicrograph showing normal viable germinal epithelium (GE) with no visible lesion seen.

Plate 2: Effect of 50 days treatment of rat with losartan on rat testis (×400)

Photomicrograph showing normal viable germinal epithelium (GE) with no visible lesion seen.

DISCUSSION

This study has shown that the treatment of rats with losartan caused no significant changes in body weight of rats. This suggests that losartan was not toxic to the animals. This could also be due to the absence of androgenic property in this drug, since it has been reported that androgens possess anabolic activities. It could also be due to absence of anorectic and lipolytic properties in this drug. Similar result was reported by in Vernonia amygdalina extract treated rats.

The drug caused no significant change in testosterone level. This probably indicates that losartan did not inhibit the mechanism involved in the process of hormone synthesis in the Leydig cells. Contrary report was given by in rats treated with aspirin.

Losartan caused significant decrease in sperm motility. This suggest that the drug was able to permeate the blood-testis barrier with a resultant alteration in the micro-environment of the seminiferous tubules, since it has been reported that the decrease in sperm motility caused by chemical agents was due to their ability to permeate the blood-testis barrier and thus creating a different micro-environment in the inner part of the wall of the seminiferous tubules from the outer part. Similar report was given by in rats treated with sarcotemma acidum extract.

There was an insignificant decrease in sperm viability as well as a significant increase in the percentage of morphologically abnormal sperm cells induced after treatment of rats with losartan. This could be due to the ability of the drug to either interfere with the spermatogenic processes in the seminiferous tubules and epididymal functions which may result in alteration of spermatogenesis. Similar result was reported by in isolated tetracyclic steroid treated rats.

Sperm count is considered to be an important parameter with which to access the effect of chemicals on spermatogenesis. Spermatogenesis is influenced by the hypothalamic adenohypophysial-Leydig cell system relating gonadotropin releasing hormone, luteinizing hormone and androgen. This implies that the decrease in sperm count caused by losartan in the treated rats might not be as a result of plasma level of testosterone, because this hormone has been reported to be important in the initiation and maintenance of spermatogenesis. Similar report was given by in Terminalia chebula extract treated rats.

Photomicrographs revealed that rats treated with losartan presented with normal germinal epithelium with no visible lesions. Similar results were reported by in rats treated with Hibiscus macranthus and Basella alba extracts. This suggests that losartan has no toxic effect on the exocrine function of the testes at histological level.

CONCLUSION

In conclusion, this study has shown that losartan has spermatotoxic or anti spermatogenic effect in male rats. However, the effect of this drug on human reproductive functions is unknown. Nevertheless, considering these findings in animal models, it is recommended that moderation should be exercised in the consumption of this drug by those taking it for therapeutic purposes.
