ABSTRACT

The present study was undertaken to evaluate the cardioprotective effect of hyroalcoholic extract of Semecarpus anacardium nuts (SANE) against isoproterenol (ISO) induced myocardial damage in rats. Rats of either sex were administered SANE (100 and 500 mg/kg) for three weeks and propranolol (PRO, 10 mg/kg) for one week orally in their respective groups. Myocardial damage was induced by subcutaneous administration of isoproterenol (150 mg/kg) for two consecutive days. A change in biomarkers and antioxidants defense system were observed in animals treated with low and high doses of SANE as well as PRO compared to ISO control. The LDH activity were significantly reduced in serum with both and high doses of SANE while no change was noted in heart tissue with both doses compared to ISO control. Further, high and low doses of SANE caused significant elevation in SOD and CAT activities compared to ISO control. Hence it is concluded that semecarpus anacardium possess potential to ameliorate the myocardial damage induced by isoproterenol in rats.

Keywords: Semecarpus anacardium; Antioxidants; Cardioprotection; Isoproterenol. Myocardial infraction

INTRODUCTION

Myocardial infarction (MI) is an acute or chronic form of cardiac disability arising due to the imbalance between the myocardial supply and demand for oxygenated blood1. MI causes irreversible necrosis of heart tissue that is responsible for the principle cause of death in developed and developing countries2. MI is making increasingly important contribution to mortality statistics due to advanced life style in developing countries, such as India, particularly in metropolitan cities of such countries3. Recently the use of herbs and herbal medicines in chronic diseases like MI is burgeoning in many parts of the world4.

Semecarpus anacardium belongs to family family Anacardiaceae that usually found in outer Himalayas from Sutlej to Sikkim, and throughout the hotter parts of India, as far east as Assam. In Ayurvedic, Unani and Siddha system of medicine, it is called as Bhallataka, Bhilaavaa, and Sorankottai respectively. The parts generally used are detoxified nut and oil5. The nut of Semecarpus shell contains biflavonoids, biflavone A, C, A1, A2, tetrahydrobustafiaflavone, jeedilflavone, semecarpulfavone and gulluflavone. Oil from nuts contains Bhilavinol and the leaves contain amentoflavone as a sole biflavonoid6. The fruit of this plant is traditionally used as a folk remedy in certain regions of India for the treatment of piles in non – bleeding conditions. It is an effective adjuvant in the treatment of ascites and tumours. It reduces the bronchospasms and their frequency too7. Nuts of Semecarpus anacardium Linn. (Anacardiaceae) are known in folklore for treating various diseases such as anti-fungal7, anti-carcinogenic and anti-arthritis8. The nut of the plant proved to have protective effect in aflatoxin B1 mediated hepatocellular carcinoma through induction of in vivo antioxidant defense system9. The fruits are - acrid, bitter, astringent, weet hemogenic, emollient digestive, carminative, anathematic, purgative, liver tonic, expectorant, alternate aphrodisiac, antiarthritic, depurative, anticarcinomic, stimulant, urinary astringent, antisepctic, anti-inflammatory, cardiotonic, uterine stimulant, sudorific, febrifuge, rejuvenating and tonic8. Further, studies showed that nut extract significantly lowered blood glucose level in alloxan induced diabetic rat also in normal rats10. Furthermore, the nut extract demonstrated antioxidant11 and anti atherosclerotic properties12.

Till now there is no scientific evidence of cardioprotective activity of Semecarpus anacardium. Therefore the current research was designed to evaluate cardioprotective role of semecarpus anacardium in an experimental model of isoproterenol (ISO) induced myocardial damage in rat heart.

MATERIALS AND METHODS

Chemicals

Isoproterenol was purchased from Sigma-aldrich, U.S.A. LDH & CKMB Kits for enzyme estimation were purchased from Crest Biosystems, Coral clinical systems, Goa, India. Other chemicals used were obtained from SD fine chemicals Ltd. (Mumbai, India). All chemicals used in the present study were of analytical grade.

Experimental animals

Laboratory bred Sprague-Dawley (SD) rats weighing 175-250 g were housed at 25° ± 5°C in a well-ventilated animal house under 12:12 h light dark cycle. Institutional Animal Ethics Committee approved the experimental protocol (KCP/IAEC-27/2008-09). The animals were maintained under standard conditions in an animal house as per the guidelines of Committee for the Purpose of Control and Supervision on Experiments on Animals (CPCSEA).
Plant material
The shade-dried nuts of *Semecarpus anacardium* were purchased from the local market of Bangalore (India) and Regional Research Institute (Ay), Bangalore authenticated the nuts (RRI/BNG/SMP/Drug Authentication/2009-10/535). The nuts were mechanically grinded and detoxified with the solvent n-butanol for five days with the daily change of the solvent. The detoxified nuts were subjected to exhaustive extraction in a soxhlet apparatus using ethanol. The extract was concentrated in water bath and stored in a desicator until further use.

**Phytochemical estimations of the extract**

Hydroalcoholic extract of *Semecarpus anacardium* nuts (SANE) was subjected to qualitative analysis to investigate the presence of various phytochemical constituents like alkaloids, carbohydrates, glycosides, phytosterols, proteins, saponins, tannins and flavonoids.

**Acute toxicity study**
The acute oral toxicity study was performed according to the OPPTS guidelines (Office of Prevention, Pesticide and Toxic Substance) following the limit test procedure. The animals were fasted over night prior to the experiment. Test dose of 2 g/kg and 5 g/kg were given orally to mice. Both doses were found to be safe. Hence 1/10th and 1/50th of the maximum safe dose corresponding to 500 and 100 mg/kg orally were selected as high and low doses respectively.

**Experimental protocol**
The animals were divided into five groups of eight each. Group I and Group II received saline for three weeks and termed as normal control and ISO control respectively; Group III was treated with standard Propranolol (PRO) 10 mg/kg, p.o for one week after two week of saline treatment; Group IV and Group V were administered SANE 100 and 500 mg/kg orally respectively for three weeks.

Isoproterenol (ISO) induced myocardial necrosis in rats
After the treatment of animals for three weeks from group II to V according to the protocol, isoproterenol (ISO) 150 mg/kg, s.c was administered for two consecutive days. Forty eight hour after the first dose of ISO administration the rats were sacrificed. Blood samples were collected by the retro orbital puncture method. Serum was separated and biochemical markers LDH and CKMB were estimated. Heart tissue homogenate (HTH) was prepared in sucrose solution (0.25 M) and used for estimation of endogenous marker enzymes and biological antioxidants viz., superoxide dismutase (SOD) catalase and TBRS activities.

**Statistical analysis**
Results are expressed as mean ± SEM. Statistical significance was assessed using One-way Analysis of variance (ANOVA) followed by Tukey-Kramer multiple comparison tests. P<0.05 was considered significant.

**RESULTS**

**Preliminary phytochemical investigation**
The preliminary phytochemical investigation of the SANE extract showed the presence of alkaloids, carbohydrates, flavonoids, cardiac glycosides, proteins, saponins, tannins and terpenoids. The percentage yield of SANE was found to be 24%.

**Effect on LDH activity (Table 1)**
The LDH activity of SANE-100 and SANE-500 were compared with normal and ISO control. No significant change in the serum LDH activity was observed with SANE-100, SANE-500 and PRO compared with normal control, whereas, significant fall in serum LDH activity was seen with PRO, SANE-100 and SANE-500 compared with ISO control. Two doses of ISO caused significant fall in LDH activity in heart tissue homogenate compared to normal control. However, no significant change occurred in groups treated with SANE-100, SANE-500 and PRO compared to ISO control.

All values are mean ± SEM, n=8, *P<0.1, **P <0.01, ***P <0.001 when compared to normal control; *P <0.1, **P <0.01, ***P <0.001 compared to ISO control. SANE -100 (Semecarpus anacardium nut extract 100 mg/kg), SANE -500 (Semecarpus anacardium nut extract 500 mg/kg). All treatments were done for 21 days by oral route.

Effect on CK-MB activity (Table 1)

Two doses of ISO resulted in extremely significant elevation in CK-MB activities in serum and fall in heart tissue homogenate. Comparing the treatment groups viz. SANE-100, SANE-500, PRO with the ISO group, an extremely significant decrease (p<0.001) in CK-MB activity in serum was observed. In heart tissue homogenate, there was an extremely significant (p<0.001) decrease in CK-MB activity were seen in ISO group compared to normal control. On the contrary, pre-treatment of animals with SANE-100, SANE-500 and PRO caused significant (p<0.001) increase in the level of CK-MB compared to ISO control.

Effect on SOD and Catalase (Table 2)

The SOD and Catalase activity were estimated in the heart tissue homogenate. Subcutaneous administration of ISO caused significant fall in SOD and CAT activities in heart tissue homogenate compared to normal control. Prophylactic administration of PRO and SANE-500 resulted in significant (p<0.001) rise in SOD and CAT activities as compared to ISO control where as SANE-100 causes no significant changes compare with ISO group.

Effect on TBARS (Table 2)

TBARS levels increased significantly (p<0.001) upon ISO administration and remained high in PRO and SANE-100 pretreated groups compared to normal control. In SANE-500 group an extremely significant decrease (p<0.001) was observed as compared to ISO group.

DISCUSSION

Isoproterenol, which is known as a synthetic catecholamine and β-adrenoceptor agonist, is reported to produce myocardial infarction in large doses. Isoproterenol causes the cardio toxicity by several mechanisms including relative hypoxia, coronary microcirculatory disturbances however intracellular calcium load is now the most accepted cause of catecholamine cardio toxicity. Two consecutive doses of isoproterenol by subcutaneous leads to an increase in calcium uptake and energy consumption leading to cell death. Elevation in the level of marker enzymes in serum is due to the leakage of enzymes from the heart as a result of isoproterenol-induced necrosis. Isoproterenol also causes the production of cytotoxic free radicals through its auto-oxidation. It has been suggested that the oxidative products of catecholamines produce changes in the myocardium by stimulating lipid peroxidation and cause irreversible damage to the myocardial membrane. This alters membrane permeability, leading to the loss of function and integrity of myocardial membranes.

As discussed above ISO induces free radical formation (TBARS) and reduction in antioxidant activities such as superoxide dismutase (SOD) and Catalase and also reduction in marker enzyme such as LDH and CKMB in HTH. Pretreatment of animals with low dose of SANE (100 mg/kg, p.o) produces no significant changes in antioxidant activities compare with the ISO group. High dose of SANE (500 mg/kg, p.o) causes significant level of elevation in SOD activities with simultaneous increase in CAT and TBARS activity, increased SOD activity may lead to intracellular accumulation of H₂O₂ with detrimental effects. Hence simultaneous rise in SOD and CAT scavenger free radicals more effectively.

It has been known that biochemical markers are tissue specific and leak from the damaged tissue. Damage to the membrane induced by the ISO causes release of enzymes in the serum and deficiency of enzymes in HTH reflects the damage to the myocardium. Low and high doses of SANE (100 & 500 mg/kg, p.o) decreases serum CKMB and both the doses causes increase in CKMB activities in HTH. In LDH activity both the high and low dose of SANE causes rise in serum but no significant change is observed in LDH activity in heart tissue homogenate.

CONCLUSION

From our study it may be concluded that the both high dose of SANE (500 mg/kg) and low dose of SANE (100 mg/kg) possess good cardiac protective activity against isoproterenol (ISO) induced myocardial necrosis in rats. Further studies should be carried out to elucidate the active constituents responsible for the said effect with extensive evaluations of histological and ultra structural changes.
