**ABSTRACT**

This study was designed to investigate the effect of captopril on reproductive parameters in male Wistar rats. Ten male Wistar rats (120 - 140 g) were divided into control (distilled water) and captopril-treated (0.71 mg/kg) groups (5 per group) for hormonal assay, andrological and Histopathological studies. The animals were orally treated on daily basis for 50 days. Plasma testosterone level was assayed using Enzyme-linked Immuno-sorbent Assay (ELISA) and semen analysis was done microscopically. Histology of testes was also done. Data were analyzed using descriptive statistics and student’s t-test at p<0.05. Treatment of rats with captopril (0.71 mg/kg) caused no significant (p>0.05) change in testosterone level relative to control. Treatment of rats with captopril (0.71 mg/kg) caused significant (p<0.05) reduction in progressive sperm motility, but induced insignificant (p>0.05) reduction sperm count relative to their respective controls. It can therefore be concluded that captopril probably has deleterious effect on the reproductive function in male rats.

**Keywords:** Captopril, Rats, Sperm count, Sperm motility, Testosterone.

**INTRODUCTION**

Captopril is an angiotensin-converting enzyme (ACE) inhibitor used for the treatment of hypertension and some types of congestive heart failure. They are used for long-term management of patients with congestive heart failure, as well as diabetic and non-diabetic nephropathies.

Captopril free radical scavenger action reduction of oxidant stress and anti-fibrotic effect has been postulated. It has been shown that captopril increases the activity of liver superoxide dismutase and glutathione peroxidase, which are of the main anti-oxidant enzymes found in aerobic organisms, in vitro independently of ACE inhibition. This activity protects cells from oxidative damage, although the mechanism is not fully understood. Its antitussive effect in rat has been reported.

Captopril has been reported to reduce blood pressure and cardiac mass, and promotes a small but significant increase in cardiac capacity for oxidation of fatty acids and reduction of glucose phosphorylation. Its effect on cardiac and renal damages, and metabolic alterations in the nitric oxide-deficient hypertensive rat has been reported. Its protective effect on cisplatin induced hepatotoxicity in rat has been reported. Its effect on glucose transport improvement in skeletal muscle of obese Zucker rats has also been reported. Captopril ameliorates the decreased Na+-K+-ATPase activity in the retina of streptozotocin-induced diabetic rats. However, due to scanty information from literature on the effect of captopril on reproductive parameters in male rats, this study therefore aims at investigating the effect of this antiarrythmic agent on these aforementioned parameters in male rats.

**MATERIALS AND METHODS**

**Experimental Animals**

Adult male rats weighing between 120 – 140 g bred in the Pre-Clinical Animal House of the College of Medicine and Health Sciences, Afe Babalola University were used. They were housed under standard laboratory conditions and had free access to feed and water; they were acclimatized for two weeks to laboratory conditions before the commencement of the experiments. All experiments were carried out in compliance with the recommendations of Afe Babalola University Ethics Committee on guiding principles on care and use of animals.

**Drug**

Captopril tablets (YanzhouXierKangtai Pharm. Co. Ltd.) were bought from Danax Pharmacy, Ibadan, Nigeria. Captopril (25 mg) was dissolved in 10 mL of distilled water to give a concentration of 2.5 mg/mL.

The dosage of captopril used in this study was in accordance with that reported by the manufacturer.

**Body Weight**

Body weight was monitored on weekly basis throughout the duration of the experiment for each rat.
Experimental Design

Ten male rats (120 – 140 g) were randomly divided into two groups, with each consisting of five animals. The two groups were subjected to the following oral treatments once a day for fifty (50) days:

Group I: received 0.5 mL/100 g of distilled water as control group.

Group II: received 0.71 mg/kg of captopril.

Collection of Blood Samples

Twenty four hours (day 51) after the last dosing of the groups, blood samples were collected from all the animals through the medial canthus for the determination of plasma testosterone levels. All the animals were later sacrificed by an overdose of diethyl ether and the testes were removed along with the epididymides for semen collection.

Hormonal Assay

Plasma samples were assayed for testosterone using the enzyme-linked immunosorbent assay (ELISA) technique using the Fortress kit.

Semen Collection

The testes were removed along with the epididymides. The caudal epididymides were separated from the testes, blotted with filter papers and lacerated to collect the semen.

Semen Analysis

Progressive sperm motility

This was done immediately after the semen collection. Semen was squeezed from the caudal epididymis onto a pre-warmed microscope slide (27°C) and two drops of warm 2.9% sodium citrate was added, the slide was then covered with a warm cover slip and examined under the microscope using x400 magnification. Ten fields of the microscope were randomly selected and the sperm motility of 10 sperms was assessed on each field. Therefore, the motility of 100 sperms was assessed randomly. Sperms were labeled as motile, sluggish, or immotile. The percentage of motile sperms was defined as the number of motile sperms divided by the total number of counted sperms (i.e. 100).

Sperm viability (Life/dead ratio)

This was done by adding two drops of warm Eosin/Nigrosin stain to the semen on a pre-warmed slide, a uniform smear was then made and air-dried; the stained slide was immediately examined under the microscope using x400 magnification. Five fields of the microscope were randomly selected and the types and number of abnormal spermatozoa were evaluated from the total number of spermatozoa in the five fields; the number of abnormal spermatozoa was expressed as a percentage of the total number of spermatozoa.

Sperm morphology

This was done by adding two drops of warm Walls and Ewas stain (Eosin/Nigrosin stain can also be used) to the semen on a pre-warmed slide, a uniform smear was then made and air-dried; the stained slide was immediately examined under the microscope using x400 magnification. Five fields of the microscope were randomly selected and the types and number of abnormal spermatozoa were evaluated from the total number of spermatozoa in the five fields; the number of abnormal spermatozoa was expressed as a percentage of the total number of spermatozoa.

Testicular Histology

After removing the testes, they were immediately fixed in Bouin’s fluid for 12 hours and the Bouin’s fixative was washed from the samples with 70 % alcohol. The tissues were then cut in slabs of about 0.5cm transversely and were dehydrated by passing through different grades of alcohol: 70 % alcohol for 2 hours, 95 % alcohol for 2 hours, 100 % alcohol for 2 hours, 100 % alcohol for 2 hours and finally 100 % alcohol for 2 hours. The tissues were then cleared to remove the alcohol; the clearing was done for 6 hours using xylene. The tissues were then infiltrated in molten Paraffin wax for 2 hours in an oven at 57°C, thereafter the tissues were embedded. Serial sections were cut using rotary microtone at 5 microns (5μm). The satisfactory ribbons were picked up from a water bath (50-55°C) with microscope slides that had been coated on one side with egg albumin as an adhesive and the slides were dried in an oven. Each section was deparaffinized in xylene for 1 minute before immersed in absolute alcohol for 1 minute and later in descending grades of alcohol for about 30 seconds each to hydrate it. The slides were then rinsed in water and immersed in alcoholic solution of hematoxylin for about 18 minutes. The slides were rinsed in water, then differentiated in 1% acid alcohol and then put inside a running tap water to blue and then counterstained in alcoholic eosin for 30 seconds and rinsed in water for a few seconds, before being immersed in 70 %, 90 % and twice in absolute alcohol for 30 seconds each to dehydrate the preparations. The preparations were cleared of alcohol by dipping them in xylene for 1 minute. Each slide was then cleaned, blotted and mounted with DPX and cover slip,
and examined under the microscope. Photomicrographs were taken at x40, x100 and x400 magnifications.

**Statistical Analyses**

The mean and standard error of mean (S.E.M.) were calculated for all values. Comparison between the control and the treated group was done using student’s t-test. Differences were considered statistically significant at p<0.05.

**RESULTS**

**Effect on Body weight**

Treatment of rats for fifty days with captopril (0.71 mg/kg) produced no significant (p>0.05) changes in body weight throughout the duration of treatment (Figure 1).

**Effect on Plasma Testosterone Level**

Treatment of rats for fifty days with captopril (0.71 mg/kg) produced no significant (p>0.05) change in testosterone level relative to control (Figure 2).

**Effect on Sperm Characteristics**

The effect of 50 days treatment of rats with captopril (0.71 mg/kg) on sperm characteristics are shown in Figures 3 and 4.

Treatment of rats with captopril (0.71 mg/kg) for 50 days caused significant (p<0.05) reduction in progressive sperm motility, but produced no significant (p>0.05) changes in the percentages of viable sperms and abnormal sperms as well as sperm count relative to their respective controls.

**Histopathological Effect**

Figures 5 and 6 respectively show the transverse sections through the testes of control rat and rat treated with captopril (0.71 mg/kg) for fifty days.

Treatment of rats with captopril (0.71 mg/kg) caused no visible lesion in the testes of rats, which is similar to what was observed in the control rats.
Figure 5: Effect of 50 days treatment of rat with distilled water (control) on rat’s testis (×400).
Photomicrograph showing normal viable germinal epithelium (GE) with no visible lesion seen.

Figure 6: Effect of 50 days treatment of rat with captopril (0.71 mg/kg) on rat’s testis (×400).
Photomicrograph showing normal viable germinal epithelium (GE) with no visible lesion seen.

DISCUSSION
This study has shown that the treatment of rats with captopril caused no significant changes in body weight of rats. This suggests that captopril has no effect on the catabolism of lipids in the adipose tissue, resulting in insignificant changes in body weight. Contrary results were reported by 13 in Persea americana leaf extracts treated rats.

The drug caused no significant change in testosterone level. This probably indicates that captopril has no effect on the hypothalamus-pituitary-gonadal axis, since it has been reported that hypothalamus-pituitary-gonadal axis increases Leydig cell numbers and stimulates their testosterone production through up-regulating LH. 14 Contrary report was given by 15 in rats treated with Fumaria parviflora leaf extract.

Captopril caused significant reduction in sperm motility. This suggests that the drug has an inhibitory effect on fertilizing capacity, since it has been reported that sperm motility is of importance with regard to sperm fertilizing capacity. 16 Similar report was given by 17 in rats treated with Pueraria tuberosa root extract.

There was no significant change in sperm viability after treatment of rats with captopril, which probably indicates that the drug has no significant effect on fertility capacity, since it has been reported that generally, fertility capacity is positively correlated to percentage live ability of the sperm cells. 18 Contrary result was reported by 19 in isolated tetracyclic steroid treated rats.

There was no significant change in the percentage of morphologically abnormal sperm cells after treatment of rats with captopril, which probably indicates that the drug has no significant effect on fertility, since it has been reported that sperm morphology is an essential parameter that reflects the degree of normality and maturity of the sperm population in the ejaculate and correlates with fertility. 20 Defects of the head and mid-piece have been classified as primary defects of spermatogenesis 21, and arise during testicular degeneration. 22 Primary defects of spermatogenesis are more likely to be associated with decreased fertility. 21 Contrary result was reported by 23 in flavonoid Cuscutae treated rats.

Sperm count, motile sperm count and normal sperm morphology have been reported as indices of male fertility. 24 The insignificant change in sperm count induced by captopril in the treated rats could be an indication that this drug does not have the potential to alter the processes of spermatogenesis by causing damage to important testicular cells such as Sertoli cells. 25 Contrary report was given by 26 in Camellia sinensis extract treated rats.

Photomicrographs revealed that rats treated with captopril presented with normal germinal epithelium with no visible lesion. This suggests that captopril has no toxic effect on the exocrine function of the testes at histological level. Similar result was reported by 27 in rats treated with Cadmium chloride.

CONCLUSION
In conclusion, this study has shown that captopril has spermatotoxic or antispermatogenic effect in male rats; However, considering these findings in animal model, it is recommended that moderation should be exercised in the consumption of this drug by those taking it for therapeutic purpose.
