ABSTRACT
Liver is the principle organ for maintaining the body's internal environment. There is currently no way to compensate for the absence of liver function. Its key impact is on the flow of nutrients and controls the metabolism of carbohydrate, protein and fats. There are many traditional as well as allopathic medicines available which report hepatoprotection but the treatment of chronic liver disease is still a challenge for health care professionals. Drugs are an important cause of liver injury. More than 900 drugs, toxins, and herbs have been reported to cause liver injury. Approximately 75% of the idiosyncratic drug reactions result in liver transplantation or death. Many types of drug induced liver diseases are acute-dose dependent liver damage, acute fatty infiltration, cholestatic jaundice, liver granulomas, active chronic hepatitis, liver cirrhosis, liver tumors etc. In the United States, approximately 2000 cases of acute liver failure occur annually and drugs account for over 50% of them (37% are due to acetaminophen, 13% are idiosyncratic reactions due to other medications). This review light on various drugs which induce hepatotoxicity, their test mechanism of liver damage, hepatoprotective herbs and clinical scenario.

Keywords: Hepatotoxicity, hepatoprotection, medicinal plants, drug metabolism, Ayurveda, mechanism etc.

INTRODUCTION
The liver is an important and largest organ of the human body. It starts developing in the human embryo between the 3rd and the 4th week of life, and it is the main site of hematopoiesis in the intrauterine period. The healthy human liver has weight around 1500 g, and it is located in the upper right corner of the abdomen and beneath the diaphragm1.

The human liver consist of constitutes about 2.4% of total body weight four lobes have unequal in shape and connected with two hepatic blood vessels called as hepatic artery and hepatic portal vein look like reddish brown in color. Two types of cells are present in hepatic lobes i.e. parenchymal and nonparenchymal cells. Liver has mainly two nonparenchymal cells in hepatic sinusoid like a sinusoidal endothelial cell and kuffer cells2.

The liver delivers crucial processing during the bile production. Bile is a mixture of water and salts, and additionally also contain cholesterol and bilirubin which produced by Hepatocytes present in the liver, with help of a hormone called cholecystokinin release from duodenum cell lines during the digestion food. It is mainly responsible for carbohydrate, lipids, and proteins metabolism and converts these biomolecules into biologically useful mater and removes several potentially toxic substances from the body via excretion process. The liver facilitates the storage of various important nutrients, vitamins, and minerals.
from food sources. Several vital protein components of blood plasma are synthesized through liver mediated process and also enhances the immune process of body with help of Kupffer cells."}

**Epidemiology**

**Indian population**

Liver cirrhosis is newly diagnosed in India affected around 10 lakh people every year. As per the World Health Organization, Liver diseases are the one of the tenth most common cause of death in India. According to the latest WHO data published in may 2014, caused by liver disease in India reached 2.44% of total deaths.

**Worldwide affected population**

In the European (EU) region approximately 29 million people affected from a chronic liver disease and approximately 30 million people are affected from the same condition in America. It was estimated that in 2013, liver cirrhosis resulted in 170,000 deaths in Europe. Alcoholic liver disease (ALD) causes liver cirrhosis as a result in 2010, 493,300 deaths was reported (156,900 female and 336,400 male). In context to Liver cancer many published reports revealed that it is the most common cause of cancer death in current scenario of life style all over the world. In, 2015 as per the report of W.H.O. there are 788,000 deaths occurred due to liver cancer globally. Out of more which more than 25,000 liver transplants were conducted globally in between 2014-2015 and more than 5000 liver transplants were performed each year in Europe only.

**Hepatic metabolic functions**

**Carbohydrate metabolism**

Liver regulate the blood glucose level to maintain by the help of conversion of glucose to glycogen when blood glucose level is high glycogenolysis and when blood glucose level is low glucogenolysis. It also helps to maintained blood glucose level during fasting or starvation via converting various amino acid and lactic acid in glucose.

**Lipid metabolism**

Liver play crucial role to store some triglycerides via breakdown of fatty acid into acetylcoenzyme A, this process known as oxidation and convert large amount of acetyl co-enzymes A into ketone bodies which is known as ketogenesis.

**Protein metabolism**

The liver plays a crucial role in ATP production via eliminating the amino group, (NH₂) from amino acids. It also play important role in conversion of the toxic ammonia (NH₃) into less toxic urea and excreted out through urine. Most of the blood plasma proteins which are mainly involve in immune response and inflammatory process are synthesized from hepatic cells.

**Hematological function**

Liver plays an important role in the production of most of the blood clotting factors in combination with anti-thrombin. It facilitates the inflammatory mediator protein for wound healing as well as immune modulation.

**Secretion and excretion of bile**

Bile is an excretory product of the hepatic system which secretes 800-1000ml of bile in a day consisting lots of salts and metabolites used for digestion. Bile pH varies between 7.6-8.6 bile mainly consist of several important ions responsible for cellular membrane processing related to digestion.

**Insulin metabolism**

The liver plays an important role in the breakdown of insulin and other hormones. Glucuronidation of bilirubin facilitate by the liver and its excretion into bile. The liver also breakdown or modified toxic substances.

**Other storage functions**

The liver facilitates the storage of various multidisciplinary substances, those are responsible for basic body building functions including glucose, vitamins A, D and B₁₂, metallic nutrients such iron, and copper.

**Causative agent of induce liver disease**

**Etiology of hepatic disorder**

**Infection**

Viruses are mainly responsible for causing liver damage and can be spread out through blood or semen, contaminated food or water and via nosocomial infections. There are few common types of liver infection causing hepatitis through viruses are including; Hepatitis A, Hepatitis B, and Hepatitis C.

**Immune system induced hepatic disorders**

There are various diseases in which our own body immune system attacks from unknown parts of the body (autoimmune) and disturb the native functions of liver. The classical example of most common autoimmune liver disease is Auto immune hepatitis.

**Genetic disorders**

Our genetic system is also playing an important role during many disease courses. An abnormal inherited gene may cause serious unwanted synthesis of harmful substances that responsible for liver damage. The commonly known genetic liver diseases are Hemochromatosis and Wilson's disease in which excess iron and copper deposition occur in the body.

**Cancer induced hepatic disease**

Cancer is the most fatal disorder of human body. Liver has also different types of cancer such as, Bile duct cancer, Hepatocellular carcinoma, and cholangio-carcinoma. Many published report suggested that the different types
of liver cancer occurs through viral infections, high dose of low-grade alcohol intake, unaware medicine intake etc.

**Other condition**

Additionally, there are various common causes of hepatotoxicity including, excessive alcohol intake, unethical drugs intake, Fat accumulation in the liver multiple use of shared injection, chemical dyes, transfusion of blood and its exposure to other people, diabetes and obesity.  

**Fatty liver condition**

Fatty liver disease is a condition where neutral fat deposited in large vacuoles of hepatic cells via the process of steatosis. It has multiple causes, in which one of the most common causes is excessive alcohol intake.  

**Jaundice**

Jaundice is a hepatic condition in which various symptoms appear including discoloration of skin and sclera to light yellow which is occur due to high level of bilirubin in to the blood. Normally bilirubin level in human blood plasma is 1mg/dL. When the concentration of bilirubin is higher approximately 1.8mg/dL or above it leads to jaundice. There are mainly three types of jaundice conditions, Pre-hepatic (hemolytic jaundice), Hepatocellular (hepatic jaundice) and Post-hepatic jaundice.  

**Liver Cirrhosis**

Cirrhosis is a disease condition in which normal liver tissues are replaced by fibrosis process and regenerative nodules that lead towards dysfunction of liver. Main cause of cirrhosis is alcohol, hepatitis viruses, and high fat deposition.  

**Hepatitis**

Hepatitis is mainly caused by virus mediated infections, in which inflammation of the liver occurred due immune response of the body. It may be reversible by self-healing process or can progress to fibrosis and cirrhosis. There are two forms of hepatitis i.e., acute and chronic. It is further divided in to two types.  

**Infectious hepatitis**

In this type of hepatitis mainly viruses are responsible behind the infections which are spread through person to person. There is various type of hepatitis based on different agents such as Hepatitis A, B, C, D, E and X.  

**Non-infection hepatitis**

Mainly primary compounds itself not cause hepatitis but there are many molecules or drugs metabolites causes liver disease such as excessive intake of alcohol or other toxic material, unethical medication or chemicals consumption are more prone towards hepatotoxicity due to which hepatitis occurs under the non-infectious hepatitis.  

**Hepatocellular carcinoma**

It is the abundant form of liver cancer. There are several different causes of hepatic cancer such as viral hepatitis infection or cirrhosis, inherited genetic disorder etc. It is commonly known as primary liver cancer or hepatoma.

### Table 1: Characterization of liver disorder and etiologic condition

Hepatotoxicity
Hepatotoxicity is a type of liver dysfunction or damage liver of which is associated with improper uses of antibiotics and potent drugs. Those chemicals which cause liver injury are called hepatotoxins or hepatotoxic agents.

Non-ionizing radiation (visible light, UV radiation, radio wave) - Directly associated with metabolic syndrome.

6. Diet
   - Alcohol - Damage the living tissue.
   - High-fat diet - Damages the central vein, endothelium & sinusoids.

Biochemical analysis parameters
Serum samples were collected and analyzed for hepatic disorders as follow.

Blood Bilirubin Test
Bilirubin level increased in many liver diseases.

Urine Bilirubin
This test is confirming the amount of bilirubin in urine.

Blood Ammonia
Determine the quantity of ammonia in the blood of patient.

AST (Aspartate Aminotransferase)
Determine the amount of AST enzyme in the blood serum.

ALT (Alanine Aminotransferase)
Determine the amount of ALT enzyme in the blood.

ALP (Alkaline Phosphatase)
The ALP test will help to determine the level of enzymes in liver disease. In many cases level of ALP is too high.

Albumin in Serum
Albumin quantity by serum analysis. Albumin is an important protein for drug binding and its transportation. Hence, the level of albumin triggers many metabolic processes in the body.

Globulins in Blood
Globulin are an important protein in mammalian body which play vital role in immune system. Low levels of globulin indicate towards liver dysfunction.

Serum Prothrombin Time
This test is to measure the time of our blood clotting which directly give the sign of liver disease or liver metabolic dysfunction.

Management of Liver Disease

Prevention
Prevention and management is an important practice through which everyone can evade themselves from chronic liver disease such as Hepatitis A and hepatitis B. There is lots of prevention measures provided from various medical organizations which is mainly contains vaccines, practicing good hygiene, avoiding drinking tap and open water when in remote area, do not take unethical drug, cannot share injections, clearly observe the label and precautions of chemicals using in industry as well as laboratory, practicing safest sex, resist to share of personal hygiene items, such as towel, napkin, trimmer, razors, stop alcohol intake, take proper medicines and injections after exposure to hepatitis A.

Allopathic medication
Ursodeoxy cholic acid (Ursodiol), Essential phospholipids, S-adenosyl methionine, ribavirin, lamivudine, steroids, antibiotics.

Ayurvedic medications

Homoeopathic medicines: The homeopathic medicines are given below;

1. Scrofoloso S(S5),
2. Livome,
3. Natrum Sulphuricum 200c (Nat Sulph-200),
4. Natrum Sulphuricum 30c (Nat Sulph-30),
5. Cholesterinum 200c (Chol-200).

Hepatotoxic Model

Hepatotoxicity is a phenomenon which implies as chemical agents drive liver damage. Drug induced liver injuries is a major cause of acute and chronic liver diseases. The liver plays a central role in transforming and clearing the foods and chemicals to minimize the susceptible of these agents as toxic. Those chemicals and naturally driven agents that cause liver injury are called hepatotoxins or hepatotoxicants. Hepatotoxicants are exogenous compounds of clinical relevance and may include overdoses of certain medicinal drugs, industrial chemicals, and natural chemicals like microcystins, herbal remedies and dietary supplements. Certain drugs may cause liver injuries when they introduced even within the minimum safety concentration ranges. Most of the time reactive metabolites and immune mediated agents are more prone towards the cause hepatotoxicity rather than primary compounds for affecting hepatocytes, biliary epithelial cells and or liver vasculature.

![Figure 4](https://example.com/figure4.png)

Figure 4: Hepatotoxicity induced by single dose administration of ccl4 (1.5ml/kg body wt.)

Chemicals causing of Hepatotoxicity

Carbon tetrachloride (CCl4), Thioacetamide (TTA), Diethyl nitrosamine (DEN), Aflatoxin B1 (AFB1), Bromobenzene, Lithocholic acid, Acryl amide (AA), Acrolein (allyl alcohol), Alpha-Naphthyl Isothiocyanate (ANIT).
The study all animals were fasted overnight, 74–84 hours from L-treatment and causes change in the renal function which affects aminotransferase (AST, ALT) activity. Aminotransferase helps of capillary tube in a very gently and slowly rupture of the blood. The blood collection was carried out with the help of capillary tube in a very gently and slowly rupture of diethyl ether. The blood collection was carried out with the help of capillary tube in a very gently and slowly rupture of diethyl ether. Each animal were anaesthetized with chloroform and sacrificed under anesthesia for biochemical analysis. At the end of the experiments, the animals were separated by centrifugation at 5000 rpm for 15 min. Serum was separated and then preserved in the cuvettes at -20°C in the freezer until analysis.

**CCl₄ induced hepatotoxicity**

Carbon tetrachloride is one of the most common chemical agents used in the laboratory for the experimental study of various liver disorders at acute and chronic condition. A metabolite of CCl₄, called trichloromethyl (CCl₃) produced by CYP2E1 isozymes, combines with cellular lipids and proteins to form trichloromethyl peroxy radical which attacks lipids on the membrane of endoplasmic reticulum faster than trichloromethyl free radical that causes lipid peroxidation and lobular necrosis. A single dose of CCl₄ reaches to its peak plasma concentration within 3 - 24 hours of administration and causes change in the histological and biochemical makeup of hepatocytes. Repeated dose of CCl₄ can induce fibrosis and necrosis. Various literature reports shown that subcutaneous dose of 2 ml/kg for 2 days elevates the level of SGPT & SGOT, however if the dosing continues for 2–4 weeks fibrosis is induced leading to bridging fibrosis in 5-7 weeks and cirrhosis in 8-9 weeks 73.

**Diagnosis of Hepatotoxicity**

The liver function test is the diagnosis procedure for liver disease. It include various parameters and its normal range if any changes in its normal value that means some abnormality in the liver. Blood bilirubin, urine bilirubin, blood ammonia AST (Aspartate Aminotransferase), ALT (Alanine Aminotransferase), ALP (Alkaline Phosphatase), albumin in serum, globulins in blood, and serum prothrombin time 74.

**Blood collection**

Each animal were anaesthetized with chloroform and diethyl ether. The blood collection was carried out with the help of capillary tube in a very gently and slowly rupture of Retro orbital plexus and 2 ml blood collected in blood collection tube. The collected blood was shifted immediately to centrifugation, allowed to clot and serum was separated by centrifugation at 5000 rpm for 15 min. Serum was separated and then preserved in the cuvettes at -20°C in the freezer until analysis.

**Biomarker for hepatotoxicity**

At the end of the study all animals were fasted overnight and sacrificed under anesthesia for biochemical analysis such as, Aspartate Transaminase (AST), Alanine Transaminase (ALT) and Alkaline Phosphate (ALP), total bilirubin (TB), and total proteins (TP).

**Estimation of Serum AST or SGPT (UV-Kinetic method)**

Aspartate Transaminase (SGOT), and (ALT) Alanine Transaminase (SGPT), both are very important and sensitive markers of hepatocellular injury. If the liver cell is injured or dies, these proteins can leak out through the liver cell membrane into the circulation and serum levels will rise. The normal serum level is 10-35 Karmel units/ml. ALT reversibly catalyses amino group from alanine to α-ketoglutarate 74.

**Principle**

SGPT catalyses the transfer of amino group from L-Alanine to 2 oxoglutarate with the formation of pyruvate and L-glutamate. The pyruvate so formed is allowed to react with NADH to produce L-lactate. The rate of this reaction is monitored by an indicator reaction coupled with LDL in the presence of NADH (nicotinamide adenine dinucleotide). The oxidation of NADH in this reaction is measured as a decreasing in the absorbance of NADH at 340 nm, which is proportional to SGPT activity 74.
L-alanine + 2-Oxoglutarate $\rightarrow$ pyruvate + L-glutamate

Pyruvate + NADH $\rightarrow$ L-Lactate + NAD

Where;

ALT: Alanine amino transferase
LDH: Lactate dehydrogenase
NAD: Nicotinamide adenine dinucleotide
NADH: Nicotinamide adenine dinucleotide hydrogen

Estimation of serum ALT or SGOT (UV-kinetic method)
The levels of ALT are very high in patients of viral hepatitis and hepatic necrosis. There is 10-to-200-fold higher level of ALT in patients of post hepatic jaundice, intrahepatic cholestasis and below 10-fold in patients of metastatic carcinoma, cirrhosis and alcoholic hepatitis. AST or SGOT is a mitochondrial enzyme released from heart, liver, skeletal muscles and kidney. The normal serum level is 10-40 Karmel units/ml. AST reversibly catalyses transfer of amino group from aspartate to α-ketoglutarate.

Principle

SGOT catalyses the transfer of amino group from L-Aspartate to 2-oxoglutarate with the formation of oxaloacetate and L-glutamate. The rate of this reaction is monitored by an indicator reaction coupled with malate dehydrogenase (MDL) in which the oxaloacetate formed is converted to malate ion in presence of NADH. The oxidation of NADH in this reaction is measured as a decreasing in the absorbance of NADH at 340 nm, which is proportional to SGOT activity.

Estimation of serum total proteins

Liver cells synthesize albumin, fibrinogen, prothrombin, alpha-1antitrypsin, haptoglobin, ceruloplasmin, transferrin, alpha foetoproteins and acute phase reactant proteins. The blood levels of these plasma proteins are decreased in extensive liver damage.

Principle

The peptide bond of proteins reacts with Cu+2 ions in alkaline solution to form a blue violet complex (Biuret reaction), each copper ion complexing with 5 or 6 peptide bonds. Tarterate is added as stabilizer while iodine is used to prevent auto reduction of alkaline copper complex. The color formed is proportional to the protein concentration and absorbance is measured at 546 nm against blank reagent.
Antioxidant enzyme evaluation

The liver tissue of each rat was removed immediately, washed in saline, blotted between filter paper fold to dryness and weighed. Then the liver was homogenized in phosphate buffer (pH – 7.4) to give a 10% homogenate. Antioxidant properties like, Superoxidase (SOD), Catalase (CAT), Gamma-glutamyl transferase (GGT) and Glutathione-S-transferase (GST) were performed.

Superoxidase (SOD)

Superoxide dismutase activity was determined by measuring the inhibition in photoreduction of nitroblue tetrazolium (NBT) by SOD enzyme. The reaction mixture contained 50 mM sodium phosphate buffer (pH 7.6), 0.1 mM EDTA, 50 mM sodium carbonate, 12 mM L-methionine, 50 µM NBT, 10 µM riboflavin and 100 µL of crude extract in a final volume of 3.0 mL. A control reaction was performed without crude extract. The SOD reaction was carried out by exposing the reaction mixture to white light for 15 min at room temperature. After 15 min incubation, absorbance was recorded at 560 nm using a spectrophotometer. One unit (U) of SOD activity was defined as the amount of enzyme causing 50% inhibition of photochemical reduction of NBT.

Catalase (CAT)

Catalase activity was measured spectrophotometrically at room temperature by monitoring the decrease in absorbance at 240 nm resulting from the decomposition of H2O2. Catalase activity was measured according to the method of Aebi. One unit (U) of catalase activity was defined as the amount of enzyme that caused an absorbance change of 0.001 per min under assay conditions. The reaction mixture contained 100 mM sodium phosphate buffer (pH 7.0), 30 mM H2O2 and 100 µL of crude extract in a total volume of 3.0 ml.

Gamma-glutamyl transferase (GGT)

The specific activity of GST was expressed as µmol GSHCDNB (1-chloro-2.4-dinitrobenzene) conjugate formed/min/mg protein using an extinction coefficient of 9.6 mM-1 cm-1. The reduced GSH levels of the tissue homogenates were measured spectrophotometrically using Elman’s reagent. The activity of the enzymes and GSH were calculated to 1 g protein content of the 10,000 g supernatant fraction, which was determined by Folin phenol reagent with bovine serum albumin as the standard.

Glutathione-S-transferase (GST)

The GST levels were analyzed in the tissues using the method of Habig et al., 1974. The tissues (50mg) were homogenized in 50 mM Tris–HCl buffer, pH 7.4, and containing 0.2 M sucrose and centrifuged at 16,000g for 45 min at 4°C. The pellet was discarded and the supernatant was used as the enzyme source. The reaction mixture in a volume of 3 mL contained 2.4 mL of 0.3 M potassium phosphate buffer (pH 6.9), 0.1 mL of 30 mM CDNB and 0.1 mL of 30 mM GSH, as enzyme source. The reaction was initiated by glutathione. The absorbances were read at 340 nm against the reagent blank. The results were expressed as µM/min/mg protein. The GST levels were measured using spectrophotometrically.

Physiological parameter

Wet liver weight of liver/100 gm and body weight of experimental animals.

Determination of body weight

Animals were weighed at the start of experiment and their final body weight using an electronic balance at the end of experiment.

Determination of wet liver weight

Animals were sacrificed and livers were isolated and washed with saline and weight determined by using an electronic balance. The liver weights were expressed with respect to its body weight i.e. gm/100gm.

Histopathology of Liver

Processing of isolated liver

The animals were sacrificed and the liver of each animals were isolated and cut into small pieces, preserved and fixed in 10% formalin for two days. Then the liver pieces were washed in running water for about 12 hours to remove the formalin and were followed by dehydration with isopropyl alcohol of increasing strength (70%, 80% and 90%) for 12 hours each. Then finally dehydration is done using absolute alcohol with three changes for 12 hours each. After paraffin infiltration the liver pieces were subjected to automatic tissue processing unit. Embedding in paraffin vacuum hard paraffin was melted and the hot paraffin was poured into L-shaped blocks. The liver pieces were then dropped into the molten paraffin quickly and allowed to cool.

Biopsy of liver tissue

The blocks were cut using microtome to get sections of thickness of 5µ. The sections were taken on a micro slide on which egg albumin i.e., sticking substance was applied. The sections were allowed to remain in an oven at 60°C for 1 hour. Paraffin melts and egg albumin denatures, there by fixing of tissue to slide.

Staining

Eosin is an acid stain, hence it stains all the cell constituents pink which are basic in nature i.e., cytoplasm. Hematoxylin, a basic stain which stains all the acidic cell components blue i.e.: DNA in the nucleus.

Histopathological parameters

Histopathological profile of the liver tissues shows in Figure 6 normal hepatic cells each with well-preserved cytoplasm, prominent nucleus and nucleolus and well brought out central vein. Histopathological profile of liver in CCl4 intoxicated rats has shown the fatty degeneration of liver.
hepatocytes, hepatic cell necrosis, portal tract fibrosis and presence of fatty cyst. The sinusoids of liver were congested and the central vein of globule was constricted. Liver protection against the toxic substance as evident by normal lobular pattern with a mild degree of fatty change, absence of necrosis and lymphocyte infiltration. However, accumulation of fatty lobules (steatosis), necrosis and scattered lymph mononuclear (LMN) cell infiltrate in hepatic parenchyma were noticed in the section of animal treated with hepatoprotective drugs.

CONCLUSION

The present review is directed towards investigate the Hepatotoxicity is the foremost health difficulties over all worlds with the confluences of liver cirrhosis, chronic liver problems and drug induced liver injury which is leading cause of death in western and developing countries. The traditional system of medicines; Ayurveda, Unani, Siddha etc. can provide us valuable guidelines to the selection, preparation and application of herbal formulation for hepatic dysfunction. A large amount of medicinal plants used traditionally for immunomodulation and hepatoprotection. There is urgent need of the health professionals and scholars working in the field of pharmacology to develop an alternative medicine or diagnostic aids to cure different kinds of liver diseases spreaded in worldwide. This review also provides some of the in vivo and in vitro experimental models to evaluate new drugs, compounds and formulate some of the important hepatoprotective plants that can be further validated using the modern scientific methodology.
